

## 2. Graphical Models

- Undirected graphical models
- Factor graphs
- Bayesian networks
- Conversion between graphical models

# Graphical models

- There are three families of graphical models that are closely related, but suitable for different applications and different probability distributions:
  - ▶ Undirected graphical models (also known as Markov Random Fields)
  - ▶ Factor graphs
  - ▶ Bayesian networks

we will learn what they are, how they are different and how to switch between them.

consider a probability distribution over  $x = (x_1, x_2, \dots, x_n)$

$$\mu(x_1, x_2, \dots, x_n)$$

a **graphical model** is a graph and a set of functions over a subset of random variables which define the probability distribution of interest

- graphical model is a marriage between probability theory and graph theory that allows compact representation and efficient inference, when the probability distribution of interest has special independence and conditional independence structures
- for example, consider a random vector  $x = (x_1, x_2, x_3)$  and a given distribution  $\mu(x_1, x_2, x_3)$
- we use (with a slight abuse of notations)

$$\mu(x_1) \triangleq \sum_{x_2, x_3} \mu(x_1, x_2, x_3), \quad \text{and}$$

$$\mu(x_1, x_2) \triangleq \sum_{x_3} \mu(x_1, x_2, x_3)$$

to denote the first order and the second order marginals respectively

- we can list all possible independence structures

$$x_1 \perp (x_2, x_3) \iff \mu(x_1, x_2, x_3) = \mu(x_1)\mu(x_2, x_3) \quad (1)$$

$$x_1 \perp x_2 \iff \mu(x_1, x_2) = \mu(x_1)\mu(x_2) \quad (2)$$

$$x_1 \perp x_2 | x_3 \iff x_1 - x_3 - x_2 \iff \mu(x_1, x_2 | x_3) = \mu(x_1 | x_3)\mu(x_2 | x_3) \quad (3)$$

and various permutations and combinations of these

- warm-up exercise

- ▶  $(1) \Rightarrow (2)$

- proof:

- $$\mu(x_1, x_2) = \sum_{x_3} \mu(x_1, x_2, x_3) \stackrel{(1)}{=} \sum_{x_3} \mu(x_1) \mu(x_2, x_3) = \mu(x_1) \mu(x_2)$$

- ▶  $(2) \not\Rightarrow (3)$

- counter example:  $X_1 \perp X_2$  and  $X_3 = X_1 + X_2$

- ▶  $(2) \not\Leftarrow (3)$

- counter example:  $Z_1, Z_2, X_3$  are independent and  $X_1 = X_3 + Z_1$ ,  
 $X_2 = X_3 + Z_2$

- this hints that different graphical models are required to represent different notions of independence
- in fact, there are exponentially many possible independencies, resulting in doubly exponentially many possible independence structures in a distribution
- however, there are only  $2^{n^2}$  undirected graphs ( $4^{n^2}$  for directed)
- hence, **graphical models only capture (important) subsets** of possible independence structures

a probabilistic graphical model is a graph  $G(V, E)$  representing a family of probability distributions

1. that share the same factorization of the probability distribution; and
  2. that share the same independence structure.
- ▶ undirected graphical model = Markov Random Field (MRF)

$$\mu(x) = \frac{1}{Z} \prod_{c \in \mathcal{C}(G)} \psi_c(x_c)$$

where  $\mathcal{C}(G)$  is the set of all maximal cliques in the undirected graph  $G(V, E)$

- ▶ factor graph model (FG)

$$\mu(x) = \frac{1}{Z} \prod_{a \in F} \psi_a(x_{\partial a})$$

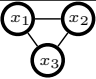

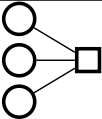

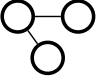

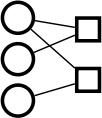

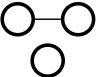

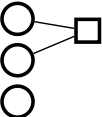

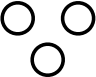

where  $F$  is the set of factor nodes in the undirected bipartite graph  $G(V, F, E)$  and  $\partial a$  is the set of neighbors of the node  $a$

- ▶ directed graphical model = Bayesian Network (BN)

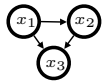

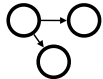

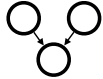

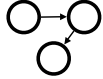

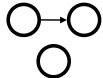

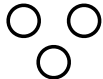

$$\mu(x) = \prod_{i \in V} \mu(x_i | x_{\pi(i)})$$

where  $\pi(i)$  is the set of parent nodes in the directed graph  $G(V, E)$

- warm-up example: Markov Random Fields (MRF) and Factor Graphs (FG)

MRF	FG	factorization	independence
		$\mu(x_1, x_2, x_3)$	none
		$\psi(x_1, x_2)\psi(x_1, x_3)$	$x_2 \perp x_3   x_1$ [HW1.1]
		$\psi(x_1, x_2)\psi(x_3)$	$x_3 \perp (x_1, x_2)$
		$\psi(x_1)\psi(x_2)\psi(x_3)$	all indep.

- warm-up example: Bayesian Network (BN) of ordering  
 $(x_1 \rightarrow x_2 \rightarrow x_3)$

BN	factorization	independence
	$\mu(x_1)\mu(x_2 x_1)\mu(x_3 x_1, x_2)$	none
	$\mu(x_1)\mu(x_2 x_1)\mu(x_3 x_1)$	$x_2 \perp x_3   x_1$
	$\mu(x_1)\mu(x_2)\mu(x_3 x_1, x_2)$	$x_1 \perp x_2$
	$\mu(x_1)\mu(x_2 x_1)\mu(x_3 x_2)$	$x_1 \perp x_3   x_2$
	$\mu(x_1)\mu(x_2 x_1)\mu(x_3)$	$x_3 \perp (x_1, x_2)$
	$\mu(x_1)\mu(x_2)\mu(x_3)$	all indep.

## Family #1: Undirected Pairwise Graphical Models

# Family #1: Undirected Pairwise Graphical Models

(a.k.a. Pairwise MRF)

$$G = (V, E), V = [n] \triangleq \{1, \dots, n\}, x = (x_1, \dots, x_n), x_i \in \mathcal{X}$$

Undirected pairwise graphical models are specified by

- ▶ Graph  $G = (V, E)$
- ▶ Alphabet  $\mathcal{X}$
- ▶ Compatibility function  $\psi_{ij} : \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}_+$ , for all  $(i, j) \in E$

$$\mu(x) = \frac{1}{Z} \prod_{(i,j) \in E} \psi_{ij}(x_i, x_j)$$

- ▶ pairwise MRF only allow compatibility functions over two variables

# Undirected Pairwise Graphical Models

Alphabet  $\mathcal{X}$

- ▶ Typically  $|\mathcal{X}| < \infty$
- ▶ Occasionally  $\mathcal{X} = \mathbb{R}$  and

$$\mu(dx) = \frac{1}{Z} \prod_{(i,j) \in E} \psi_{ij}(x_i, x_j) dx$$

(all formulae interpreted as densities)

Compatibility function  $\psi_{ij}$

$$\mu(x) = \frac{1}{Z} \prod_{(i,j) \in E} \psi_{ij}(x_i, x_j)$$

Partition function  $Z$  plays a crucial role!

$$Z = \sum_{x \in \mathcal{X}^V} \prod_{(i,j) \in E} \psi_{ij}(x_i, x_j)$$

## Graph notation

- $\partial i \equiv \{\text{neighborhood of vertex } i\},$

- $\deg(i) = |\partial i|,$

- $x_U \equiv (x_i)_{i \in U},$

$$\partial 9 = \{5, 6, 7\}$$

$$\deg(9) = 3$$

$$x_{\{1,5\}} = (x_1, x_5)$$

$$x_{\partial 9} = (x_5, x_6, x_7)$$

- Complete graph

- Clique

## Example

- Coloring (e.g. ring tone)
- Given graph  $G = (V, E)$  and a set of colors  $\mathcal{X} = \{R, G, B\}$
- Find a coloring of the vertices such that no two adjacent vertices have the same color
- Fundamental question: Chromatic number

A (joint) probability of interest is uniform measure over all possible colorings:

$$\mu(x) = \frac{1}{Z} \prod_{(i,j) \in E} \mathbb{I}(x_i \neq x_j)$$

- $Z$  = total number of colorings
- Sampling = coloring
- similarly, independent set problem [HW1.3, 1.4]

## (General) Undirected Graphical Model

Undirected graphical models are specified by

- ▶ Graph  $G = (V, E)$
- ▶ Alphabet  $\mathcal{X}$
- ▶ Compatibility function  $\psi_c : \mathcal{X}^c \rightarrow \mathbb{R}_+$ , for all maximal cliques  $c \in \mathcal{C}$

$$\mu(x) = \frac{1}{Z} \prod_{c \in \mathcal{C}} \psi_c(x_c)$$

## Family #2: Factor Graph Models

## Family #2: Factor graph models

Factor graph  $G = (V, F, E)$

- ▶ Variable nodes  $i, j, k, \dots \in V$
- ▶ Function nodes  $a, b, c, \dots \in F$

Variable node  $x_i \in \mathcal{X}$ , for all  $i \in V$

Function node  $\psi_a : \mathcal{X}^{\partial a} \rightarrow \mathbb{R}_+$ , for all  $a \in F$

$$\mu(x) = \frac{1}{Z} \prod_{a \in F} \psi_a(x_{\partial a})$$

# Factor graph models

Factor graph model is specified by

- ▶ Factor graph  $G = (V, F, E)$
- ▶ Alphabet  $\mathcal{X}$
- ▶ Compatibility function  $\psi_a : \mathcal{X}^{\partial a} \rightarrow \mathbb{R}_+$ , for  $a \in F$

$$\mu(x) = \frac{1}{Z} \prod_{a \in F} \psi_a(x_{\partial a})$$

Partition function:  $Z = \sum_{x \in \mathcal{X}^V} \prod_{a \in F} \psi_a(x_{\partial a})$

# Conversion between factor graphs and pairwise models

## From pairwise model to factor graph

A pairwise model on  $G(V, E)$  with alphabet  $\mathcal{X}$  can be represented by a factor graph  $G'(V', F', E')$  with  $V' = V$ ,  $F' \simeq E$ ,  $|E'| = 2|E|$ ,  $\mathcal{X}' = \mathcal{X}$ .

- Put a factor node on each edge

## From factor graph to a general undirected graphical model

A factor model on  $G(V, F, E)$  with alphabet  $\mathcal{X}$  can be represented by a pairwise model on  $G'(V', E')$  with  $V' = V$ ,  $E' \simeq \sum_{a \in F} |\partial a|^2$ ,  $\mathcal{X}' = \mathcal{X}$ .

- A factor node is turned into a clique

## From factor graph to a pairwise model

A factor model on  $G(V, F, E)$  can be represented by a pairwise model on  $G'(V', E')$  with  $V' = V \cup F$ ,  $E' = E$ ,  $\mathcal{X}' = \mathcal{X}^\Delta$ ,  $\Delta = \max_{a \in F} \deg(a)$ .

- A factor node is represented by a large variable node

## Family #3: Bayesian Networks

## Family #3: Bayesian networks

DAG: Directed Acyclic Graph  $G = (V, D)$

Variable nodes  $V = [n]$ ,  $x_i \in \mathcal{X}$ , for all  $i \in V$

Define  $\pi(i) \equiv \{\text{parents of } i\}$

Set of directed edges  $D$

$$\mu(x) = \prod_{i \in V} \mu_i(x_i | x_{\pi(i)})$$

Bayesian network is specified by

- ▶ directed **acyclic** graph  $G = (V, D)$
- ▶ alphabet  $\mathcal{X}$
- ▶ conditional probability  $\mu_i(\cdot|\cdot) : \mathcal{X} \times \mathcal{X}^{\pi(i)} \rightarrow \mathbb{R}_+$ , for  $i \in V$

$$\mu(x) = \prod_{i \in V} \mu_i(x_i | x_{\pi(i)})$$

- ▶ we do not need normalization ( $1/Z$ ) since

$$\sum_{x_i \in \mathcal{X}} \mu_i(x_i | x_{\pi(i)}) = 1 \quad \Rightarrow \quad \sum_{x \in \mathcal{X}^V} \mu(x) = 1$$

# Conversion between Bayes networks and factor graphs

## from Bayes network to factor graph

A Bayes network  $G = (V, D)$  with alphabet  $\mathcal{X}$  can be represented by a factor graph model on  $G' = (V', F', E')$  with  $V' = V$ ,  $|F'| = |V|$ ,  $|E'| = |D| + |V|$ ,  $\mathcal{X}' = \mathcal{X}$ .

- represent by a factor node each conditional probability
- **moralization** for conversion from BN to MRF

## from factor graph to Bayes network

A factor model on  $G = (V, F, E)$  with alphabet  $\mathcal{X}$  can be represented by a Bayes network  $G' = (V', D')$  with  $V' = V$  and  $\mathcal{X}' = \mathcal{X}$ .

- take a topological ordering, e.g.  $x_1, \dots, x_n$
- for each node  $i$ , starting from the first node, find a minimal set  $U \subseteq \{1, \dots, i-1\}$  such that  $x_i$  is conditionally independent of  $x_{\{1, \dots, i-1\} \setminus U}$  given  $x_U$ . (we will learn how to do this)
- in general the resulting Bayesian network is dense

Because MRF and BN are incomparable, some independence structure is lost in conversion

$$\mu(x) = \psi(x_1, x_2)\psi(x_1, x_3)\psi(x_2, x_4)\psi(x_3, x_4)$$

$$x_1 \perp x_4 | (x_2, x_3)$$

$$x_2 \perp x_3 | (x_1, x_4)$$

$$x_2 \perp x_3 | (x_1, x_4)$$

$$\mu(x) = \mu(x_2)\mu(x_3)\mu(x_1|x_2, x_3)$$

$$x_2 \perp x_3$$

no independence

Factor graphs are more 'fine grained' than undirected graphical models

$$\psi(x_1, x_2, x_3)$$

$$\psi_{12}(x_1, x_2)\psi_{23}(x_2, x_3)\psi_{31}(x_3, x_1)$$

$$\psi_{123}(x_1, x_2, x_3)$$

all three encodes same independencies, but different factorizations  
(in particular the degrees of freedom in the compatibility functions are  $3|\mathcal{X}|^2$  vs.  $|\mathcal{X}|^3$ )

- set of independencies represented by MRF is the same as FG
- but FG can represent a larger set of factorizations

- undirected graphical models can be represented by factor graphs
  - ▶ we can go from MRF to FG without losing any information on the independencies implied by the model
- Bayesian networks are not compatible with undirected graphical models or factor graphs
  - ▶ if we go from one model to the other, and then back to the original model, then we will not, in general, get back the same model as we started out with
  - ▶ we lose any information on the independencies implied by the model, when switching from one model to the other

## Bayes networks with observed variables

$$V = H \cup O$$

Hidden variables:  $x = (x_i)_{i \in H}$

Observed variables:  $y = (y_i)_{i \in O}$

$$\mu(x, y) = \prod_{i \in H} \mu(x_i | x_{\pi(i) \cap H}, y_{\pi(i) \cap O}) \prod_{i \in O} \mu(y_i | x_{\pi(i) \cap H}, y_{\pi(i) \cap O})$$

Typically interested in  $\mu_y(x) \equiv \mu(x|y)$  and

$$\arg \max_x \mu_y(x)$$

# Example

## Forensic Science

[Kadane, Shum, *A probabilistic analysis of the Sacco and Vanzetti evidence*, 1996]

## Example

### Medical Diagnosis

[M. Shwe, et al., Methods of Information in Medicine, 1991]

# Roadmap

Cond. Indep. $\mu(x)$	Factorization $\mu(x)$	Graphical Model	Graph $G$	Cond. Indep. implied by $G$
$x_1 - \{x_2, x_3\} - x_4;$ $x_4 - \{\} - x_7;$ $\vdots$	$\frac{1}{Z} \prod \psi_a(x_{\partial a})$	FG	Factor	Markov
	$\frac{1}{Z} \prod \psi_C(x_C)$	MRF	Undirected	Markov
	$\prod \psi_i(x_i   x_{\pi(i)})$	BN	Directed	Markov

- Any  $\mu(x)$  can be represented by  $\{\text{FG}, \text{MRF}, \text{BN}\}$
- A  $\mu(x)$  can be represented by multiple  $\{\text{FG}, \text{MRF}, \text{BN}\}$  with multiple graphs (but same  $\mu(x)$ )
- We want a ‘simple’ graph representation (sparse, small alphabet size)
  - ▶ Memory to store the graphical model
  - ▶ Computations for inference
- $\mu(x)$  with some conditional independence structure can be represented by simple  $\{\text{FG}, \text{MRF}, \text{BN}\}$
